A redução seletiva do 3-oxoglutarato de dimetila foi realizada em vários níveis. A redução quimiosseletiva da carbonila cetônica com boridreto de sódio é descrita em alto rendimento, fornecendo o 3-hidroxiglutarato de dimetila. Quando o complexo borana-dimetil sulfeto (BMS) foi empregado como agente redutor, um diol ou um triol puderam ser obtidos, respectivamente, a partir do 3-hidróxi- ou do 3-oxoglutarato, permitindo a síntese de compostos 1,3,5-oxigenados prática e eficientemente.

The selective reduction of dimethyl 3-oxoglutarate was accomplished in different levels. A high yielding sodium borohydride reduction of the keto group is fully described leading to dimethyl 3-hydroxyglutarate. When borane-dimethyl sulfide (BMS) complex was used, a diol or a triol compound can be obtained by selective or total reduction of 3-hydroxy- or 3-oxoglutarate, respectively, allowing an efficient and practical route to 1,3,5-oxygenated compounds.

Keywords: dimethyl 3-oxoglutarate, BMS complex, selective reduction, 1,3,5-oxygenated synthons

Introduction

Selectivity is imperative in modern organic synthesis, especially when multifunctional molecules are involved. The reagents and conditions employed for a chemical transformation must not affect other functional groups in the molecule, leading only to the required transformation. Among these selective procedures, reductions play an important role. Those transformations are known by their chemocompatibility, possibility of partial reduction, and regio- and stereoselectivity altered or controlled by neighboring groups, besides asymmetric transformations.

In this context, the selective reduction of dimethyl 3-oxoglutarate (1) to prepare dimethyl 3-hydroxyglutarate (2), diol 3 and triol 4 derivatives is an important approach in organic synthesis since these structures are useful intermediates in the preparation of complex molecules. A chemo-, regio-, or total reduction of dimethyl 3-oxoglutarate allow access to 1,3,5-oxygenated derivatives in different oxidation states (Figure 1), creating a family of useful synthons in fast and accessible manner. Due this, we decided to explore routes from same precursor 1 in order to prepare that family of synthons, investigating either NaBH₄ and BMS complex as reducing agents.

Figure 1. Synthesis of 1,3,5-oxygenated synthons from dimethyl 3-oxoglutarate.
Results and Discussion

Our investigation began by exploring the chemoselective reduction of commercially available dimethyl 3-oxoglutarate (1) with NaBH₄. Although also commercial, dimethyl 3-hydroxyglutarate (2), product of chemoselective reduction of 1, is more expensive,¹ and its production from 3-oxoglutarate is described either via high pressure experiments,² or in moderate yield procedures,³ or lacking experimental details.⁴ Our first attempt to the selective reduction of the keto group employed 1 equiv. of NaBH₄ in MeOH as solvent, followed by treatment with acetic acid (standard conditions, Table 1, entry 1), but disappointingly low yields were obtained. Use of different acid treatment or higher temperatures just furnishes 2 in low yields (entries 2-4). Moderate results were obtained with nearly stoichiometric reducing agent quantities (entry 6). However, high yields were obtained with the addition of 0.3 equivalents of reducing agent to a solution of glutarate 1 in MeOH, followed by aciddification with solid citric acid.⁷ 3-Hydroxy-diester 2 was isolated in 96% yield after column chromatography (entry 9).

² Isolated yield of analytically pure products.

With a well-described procedure for keto-functional group reduction in hands, our next challenge was to achieve the regioselective reduction of the ester group. Inspiration came from dimethyl maleate, where a neighboring α-hydroxy group plays a crucial role directing the reduction reaction to only one ester site.⁸ A combination of borane-dimethyl sulfide (BMS) complex with catalytic sodium borohydride was very efficient in the regioselective reduction affording methyl 3,4-dihydroxy butanoate from dimethyl maleate in 88% yield.

Chastrette and coworkers have proved to be possible to reach the complete reduction of malic esters when excess of reducing agent was employed.⁹ Indeed, the BMS complex with NaBH₄ led to the reduction of an ester site with a β-oxygenated center. In this direction, we envisaged a possibility of access mono-reduction of ester functionality, controlling the amount of BMS added, as an expedient route to the preparation of synthon 3.

Diol 3 is actually accessible either by keto-reduction and debenzylation¹⁰ of ethyl 5-benzylxylo-3-oxopentanoate,¹¹ or by organoselenium-mediated reduction of α,β-epoxy-δ-valerolactone.¹² The first approach allowed the synthesis of 2 also in asymmetric fashion, but required the preparation of precursor and high pressure apparatus, while the second method of synthesis demanded a non-commercial reagent and a specific reducing agent.

Our attempt to obtain diol 3 was based on the possibility of carboxyl reduction directed by the β-oxygenated group. We planned to use the conditions described for the reduction of dimethyl maleate to corresponding diol as substrate. Oxo precursor 1 was also employed due to the possibility of in situ synthesis of 2 by NaBH₄ reduction (Table 2, entries 1 and 2). Although 3 was selectively obtained, only moderate to low total yields were observed, along with triol 4. In order to improve yield and selectivity, an increase in the amount of NaBH₄ was evaluated. However, a decrease in yield and selectivity was observed (entries 3 and 4). Thus, we decided to investigate the BMS reduction¹³ without the addition of NaBH₄. To our delight, better results (yields and selectivities) emerged (entries 5 and 7), specially when dimethyl 3-hydroxyglutarate (2) was employed. Finally, longer reaction time revealed to be advantageous for the preparation of diol 3 in 80% isolated yield (entry 8).

With a practical and efficient procedures to synthesize alcohol 2 and diol 3 established, we directed our attention to obtain an efficient methodology for the preparation of triol 4.

Syntheses of triol 4 were centered on the hydrogenation of dimethyl 3-oxoglutarate (1) with catalyst¹⁴ or reduction with LiAlH₄.¹⁵ However, only moderate yields were obtained. An alternative and high yield preparation of triol 4 is reported but employing an expensive reagent.¹⁶ Due to this, we decided to test modifications of our previously experimental conditions to access diol 3. Firstly, 3 equiv. of BMS complex were added to 1 and 2 at room temperature, furnishing moderate yield of triol 4 (Table 3, entries 1 and 2). An investigation of the effect of temperature was also carried out (entries 3 and 4), showing a positive result in total reduction of 1 (comparing with
of synthesis of triol 4 (98% yield) was developed which employed a modified BMS reducing system.

**Experimental**

Reactions were performed using oven-dried glassware under an atmosphere of argon. Tetrahydrofuran was dried over sodium/benzophenone and freshly distilled before use. Methanol was distilled from methyl magnesium Grignard. Yields refer to chromatographically and spectroscopically pure compounds unless otherwise stated. All chromatography was carried out using slurry-packed Acros 0.060-0.200 mm silica gel. IR spectra were recorded on an ABB Bomen MB-Series GRAMS with internal referencing and selected absorption maxima ($\nu_{\text{max}}$) are reported in cm$^{-1}$. $^1$H NMR spectra were recorded on Varian Gemini 300 (300 MHz). Chemical shifts ($\delta$) are quoted in ppm, to the nearest 0.01 ppm, and are referenced to the residual non-deuterated solvent peak. Coupling constants ($\text{J}$) are reported in Hertz to the nearest 0.5 Hz. $^{13}$C NMR spectra were recorded on Varian Gemini 300 (75 MHz). Chemical shifts ($\delta$) are quoted in ppm, to the nearest 0.1 ppm, and are referenced to the residual non-deuterated solvent peak.

**Synthesis of dimethyl 3-hydroxyglutarate (2)**

To a stirred solution of dimethyl 3-oxoglutarate (1008.1 mg, 5.79 mmol) in MeOH (15 mL) at 0°C was added portion wise NaBH$_4$ (65.7 mg, 1.74 mmol). The reaction was allowed to reach room temperature and after 24 h was quenched by addition of solid citric acid until pH reached 5 to 6. To the reaction mixture was added silica gel (ca. 1g) and the solvent was distilled off. The residue was purified by column chromatography on silica gel (elution with AcOEt:hexane, 1:1) to afford the dimethyl 3-hydroxyglutarate (977.2 mg, 96%) as a colorless oil. Chemical shifts ($\delta$) are quoted in ppm, to the nearest 0.01 ppm, and are referenced to the residual non-deuterated solvent peak. IR absorption maxima ($\nu_{\text{max}}$) are reported in cm$^{-1}$. $^1$H NMR spectra were recorded on Varian Gemini 300 (300 MHz). $^{13}$C NMR spectra were recorded on Varian Gemini 300 (75 MHz). Chemical shifts ($\delta$) are quoted in ppm, to the nearest 0.1 ppm, and are referenced to the residual non-deuterated solvent peak.

**Synthesis of methyl 3,5-dihydroxypentanoate (3)**

To a stirred solution of dimethyl 3-hydroxyglutarate (200.1 mg, 1.14 mmol) in THF (3 mL) under argon at room temperature was added BH$_3$Me$_2$S (2 equiv., 216 µL, 2.28 mmol) drop to drop. After 48 h the reaction was diluted

**Conclusions**

In summary, we have reported efficient routes to 1,3,5-oxygenated pentanes with different oxidation states from the same precursor (dimethyl 3-oxopentanoate, 1). A chemoselective reduction to alcohol 2 was achieved in high yield (96%) and was fully described, while diol 3 was obtained in 80% yield from 2, allowing a fast access to this important oxygenated synthon. Finally, a superior method
with MeOH (3 mL) with intense formation of bubbles, and stirred for 1 h. The solvent was distilled off and the residue purified by column chromatography on silica gel (elution with AcOEt/hexane 4:1 to MeOH/AcOEt 1:19) to afford methyl 3,5-dihydroxy pentanoate (135.9 mg, 80%) as a colorless oil (RF = 0.3 with AcOEt as eluent).

IR νmax/cm⁻¹: 3452, 1738, 1345, 1288, 1171, 1108, 1011; 1H NMR (300 MHz; CDCl₃) δ 4.23 (quint, J 6.0 Hz, 2H), 3.67 (s, 3H), 2.90 (b, 1H), 1.68 (q, J 6.5 Hz, 2H), 1.65 (q, J 5.6 Hz, 2H), 1.50-1.30 (m, 4H); 13C NMR (125 MHz; CDCl₃) δ 173.2, 67.4, 60.5, 51.9, 41.7, 38.1.

Synthesis of 1,3,5-pentanetriol (4)

To a stirred solution of dimethyl 3-oxogluturate (200 mg, 1.15 mmol) in THF (3.5 mL) under argon at 45-50 °C was added BH₃·MeS (3 equiv., 332 μL, 3.45 mmol) drop to drop. After 48 h the reaction was diluted with MeOH (3.5 mL) with intense formation of bubbles, and stirred for 1 h. The solvent was distilled off and the residue purified by column chromatography on silica gel (elution with AcOEt to MeOH/AcOEt 1:9) to provide 1,3,5-pentanetriol (135.2 mg, 98%) as a viscous oil (RF = 0.1 with AcOEt as eluent).

IR νmax/cm⁻¹: 3348, 2944, 2888, 1422, 1062; 1H NMR (300 MHz; CDCl₃) δ 4.05-3.92 (m, 4H), 3.90 (br, 1H), 2.46 (dd, J 5.8 and 1.2 Hz, 2H), 1.65 (q, J 5.6 Hz, 2H); 13C NMR (100 MHz, CDCl₃) δ 173.2, 67.4, 60.5, 51.9, 41.7, 38.1.
